(57) Claims:

1        A device for identifying and counting paper currency, wherein the notes of paper currency stored in a first paper currency housing unit are extracted sequentially one at a time and conveyed to a second paper currency housing unit as the number of conveyed notes of paper currency is counted, and wherein said device for identifying and counting paper currency is equipped with (a) a detection unit to detect the denomination of the notes of paper currency, (b) an identifying unit to identify the denomination of the notes of paper currency based on the detection signals from said detection unit, (c) a denomination indication unit to indicate the denomination of the notes of paper currency to be counted, (d) a denomination collation device to collate the denomination indicated by said denomination indication unit and the denomination identified by said identifying unit and then output a collation signal, and (e) a conveyor control unit to control the immediate suspension or cancellation of a count operation if there is a misidentification of a denomination based on the collation signals outputted from said denomination collation device.

2        A device for identifying and counting paper currency, wherein the notes of paper currency stored in a first paper currency housing unit are extracted sequentially one at a time and conveyed to a second paper currency housing unit as the number of conveyed notes of paper currency is counted, and wherein said device for identifying and counting paper currency is equipped with (a) a detection unit to detect the denomination of the notes of paper currency, (b) an identifying unit to identify the denomination of the notes of paper currency based on the detection signals from said detection unit, (c) a denomination recording unit to record the denomination identified by said identifying unit for the first note of paper currency conveyed at the start of the count, (d) a denomination collation device to collate the denomination recorded by said denomination recording unit and the denomination identified by said identifying unit and then output a collation signal, and (e) a conveyor control unit to control the immediate suspension or cancellation of a count operation if there is a misidentification of a denomination based on the collation signals outputted from said denomination collation device.

### Detailed Explanation of the Present Invention

The present invention pertains to a paper currency processing device that extracts notes of paper currency one by one and performs the desired processing such as counting the notes of paper currency. The present invention pertains more specifically to a device for identifying and counting paper currency that accurately identifies and counts notes of paper currency.

In these types of devices, the notes of paper currency are extracted one at a time from a stack of paper currency by an extraction mechanism and then conveyed. The denomination of the notes of paper currency is identified, and the total number of notes of paper currency and the total amount of money are counted. After the desired number of notes of paper currency has been extracted, the device shuts down. At the present time, the operator has to verify the denominations of the notes of paper currency counted by the device. If the notes of paper currency with the wrong denomination are mixed in, the total number of notes of paper currency and the total amount of money displays are both incorrect. The purpose of the present invention is to provide a device for identifying and counting paper currency that automatically identifies the denominations of the notes of paper currency during the count by indicating the denomination of the notes of paper currency to be counted. If a note of paper currency with the wrong denomination is detected, the counting operation can be suspended or cancelled by the device. Another purpose of the present invention is to provide a device for identifying and counting paper currency that automatically identifies and records the denomination of the first note of paper currency conveyed at the start of the count, and then collates the denominations of the successively conveyed notes of paper currency. If a note of paper currency with the wrong denomination is detected, the counting operation can be immediately suspended or cancelled by the device.

The following is an explanation of the preferred embodiments of the present invention with reference to the drawings.

The preferred embodiment in the figures is an example of the present invention applied to paper currency counting device. In Fig. 1, the loading unit 2 is situated in the top portion of the counting device 1, and conveyor belts 3, 3 are situated on both sides of the loading unit 2 to extract the notes of paper currency.

As shown in Fig. 2, the conveyor belts 3, 3 are wrapped around pulleys 4, 5. Ribs are formed in the outside surface of the belts 3, 3 to increase the force of friction with the notes of paper currency P. The drive is applied in the direction of the arrow from the motor M and belt 6 towards pulley 5. An eccentric pulley 7 is situated in the position corresponding to the inner edge of the loading unit 2. When the portion of the eccentric pulley 7 with the wider radius 7a comes into contact with the inner surface of the running belt, the outer surface of the running belt strikes the surface of the loading unit 2. When the portion of the eccentric pulley 7 with the narrower radius 7b comes into contact with the inner surface of the running belt, the outer surface of the running belt falls short of the surface of the loading unit 2. As a result, the up and down movement of the belt 3, 3 intermittently extracts the notes of paper currency P from the bottom of the loading unit 2 one by one.

The outer surface of a reverse roller 8 comes into contact with the middle portion of the upper surface of the belts 3, 3 and rotates in the opposite direction. It rotates around a shaft 11 supported by another shaft 9 on the tip of a fixed arm 10 at intervals large enough to allow a single note of paper currency to pass between it and the belts 3, 3. A guide pulley 41 to support the position of the belts 3, 3 is situated on the bottom surface of the belts 3, 3 in the position corresponding to the reverse roller 8.

The upper portion of a pressure member 14, supported by a portion 12 of the main body 1 of the counting device and a shaft 13, is situated on the paper currency input side of the reverse roller 8 so as to be able to oscillate. The lower portion 14a comes into contact with rods 15, 15 in order to avoid contact with the outer surface of the reverse roller 8 and the belts 3, 3. It is bent at the proper angle towards the reverse roller 8 so as to straddle the reverse roller 8 and belts 3, 3 in the interval between the rods 15, 15. The lower portion 14a is inclined away from the reverse roller 8 by a spring 16.

A large diameter roller 18 is attached to the pulley shaft 17 on the drive side of the conveyor belts 3, 3 and a semicircular guide plate 19 is added to the outside half of this roller 18 to provide a small space between it and the outer surface of the roller 18. The bottom edge of the guide plate 19 is connected to a chute 20 used to guide the front edge of the notes of paper currency P, and the bottom edge of the chute 20 comes up to the upper surface of a conveyor belt 21 that is disposed horizontally. It comes up against the upper surface of this conveyor belt 21 [sic]. The other end of the conveyor belt 21 comes up to the take-out opening 22 in the main body 1 of the counting device and is configured so that the notes of paper currency P discharged from the take-out opening 22 into a paper currency collection platform 23 situated at the take-out opening 22. The base of spring-loaded pressure plates 24 fixed to the main body 1 of the counting device are attached above the paper currency collection platform 23 so that the notes of paper currency P do not fly off when discharged into the paper currency collection platform 23.

A booster plate 25 extends from near the bottom of the loading unit 2 on the front end to near the backside pulley 5 on the back end between the conveyor belts 3, 3. It is supported so as to oscillate freely on a shaft 26 that is situated slightly beyond the center of the reverse roller 8. The surface of the booster plate 25 is positioned slightly higher than the upper surface of the conveyor belts 3, 3 raised by the eccentric pulley 7 when the front end 25a is raised, and is positioned slightly lower than the upper surface of the conveyor belts 3, 3 when the front end 25a drops below the shaft 26.

The shaft 26 is attached to an arm 27 with a link 30 connecting the tip of arm 27 to the tip of arm 29 attached to shaft 28. A lever 32 is attached to this shaft 28 so as to change between two positions. In one of these positions, the grooves 31 on the bottom surface of the pressure member 14 are engaged and the bottom tip 14a of the pressure member 14 extends down the front side of the reverse roller 8. (This position is shown in Fig. 2.) In the other position, the bottom tip 14a of the pressure member 14 withdraws from front side of the reverse roller 8. In other words, part of the outer surface of the reverse roller 8 extends between the rod portion 15 of the pressure member 14. A lever 33 is attached to the tip of shaft 26, and the plunger 35 on the solenoid 34 is connected to the tip of the lever 33. When the solenoid 34 is

excited, the tip 25a of the booster plate 25 is raised and the pressure member 14 is drawn near to the reverse roller 8.

The pressure unit shown in Fig. 2 is configured in the following way. The bent portions of a pair of left and right support arms 36, 36, bent to the desired obtuse angle, lend support to shaft 9, and the tips of the support arms 36, 36 support pressure rollers 37, 37 etc. by means of shaft 47. The pressure roller 37, 37 etc. side is made heavier than the weight 38 side by the weight or aspect of the lever itself. At this time, the line running through the center of the pressure rollers 37, 37 etc. and the center of the shaft 9 is at the desired angle to the line running through the center of the weight 38 and the center of the shaft 9. The stopper 39 fixed to the arm 10 supporting the shaft 11 of the reverse roller 8 is arranged so as to freely come into contact with the upper surface near the back of the support arm 3 and determine the positional relationship between the pressure rollers 37 and the reverse roller 8. A roller 42 that freely comes into contact with the outer surface of the roller member 40 concentric to the reverse roller 8 is attached to the front end 25a of the booster plate 25. When the front end 25a of the booster plate 25 rises, the reverse roller 8 is raised to maintain a certain interval between the upper surface of the booster plate 25 and the outer surface of the reverse roller 8. As a result, notes of paper currency P left on the booster plate 25 when the conveyor is shut down can be sent back to the loading unit 2.

In this figure, 43 denotes the counting roller that comes into contact with the large diameter roller 18. When a note of paper currency P passes through these rollers 18, 43, the counting roller 43 rises. The lever 44 picks up this movement. The counting switch 45 is opened and shut by the lever 44, and the note of paper currency P passing through the rollers is counted. In the same figure, 46 denotes the emergency stop switch that is activated when the paper currency P in the collection platform 23 is full or a note of paper currency P becomes jammed inside the conveyor mechanism.

The front panel of the counting device 1 is equipped with a display unit 101 to display the total amount and the total number of notes of paper currency that have been counted, a clear key 102 to clear the money data, denomination selection keys 103 to indicate the denomination(s) of paper currency to be counted, a note

number setting unit (digital switches) 104 to set the number of notes of paper currency to be counted, denomination count selection buttons 105 to select the type of paper currency to be counted (common paper, single denominations, multiple denominations), operation mode selection buttons 106 to select the operation mode of the counting device (calculation mode, addition mode, batch mode), a total key 107 to indicate the data display of the main memory to be explained below, a subtotal key 108 to indicate the data display of the first memory to be explained below, a stop button 109 to stop all operations, and a power supply switch 110.

The control circuit shown in Fig. 3 controls this counting device. In Fig. 3, 111 denotes the pattern detection unit situated on the conveyor route used to identify the denomination of the conveyed notes of paper currency. The pattern detection unit consists of the photoelectric unit in the lighting device 111B and a scanning slot plate 111D with a long transparent slot 111C as shown in Fig. 4. In the control circuit, 112 denotes the identifier used to identify the denomination of the notes of paper currency based on the pattern detection signals from the pattern detection unit 111, 113 denotes the denomination storage unit used to store the denomination data indicated by the denomination selection keys 103, and 114 denotes the denomination collation unit used to collate the denomination identified by the identifier 112 and the denomination stored in the denomination storage unit 113. Also, 121 denotes the conveyor control unit that controls the conveyor drive unit 120 used to convey the paper currency. The conveyor drive unit 120 is operated by a start command consisting of detection signals from the first paper currency capacity detection unit 122 which detects paper currency stored in the loading unit 2. Notes of paper currency are extracted one by one from the loading unit 2 and conveyed along the paper currency collection platform 23. If a mismatch is indicated by the collation signals RF from the denomination collation unit 114, the conveyor drive unit 120 is stopped. When a stop signal is inputted using the stop button 109, the conveyor drive unit 120 is stopped even when the conveyor is still in operation.

The control circuit also has a wrong denomination paper currency discharge unit 123. If a mismatch is indicated by the collation signals RF from the denomination collation unit 114, the detected note of paper currency is not conveyed to the paper currency collection platform 23 but may be discharged from a

discharge slot. Also, 124 denotes an error detection unit that detects signals for the paper currency stored in the loading unit 2 as generated by the first paper currency capacity detection unit 122, and outputs an error detection TD for a mistaken note of paper currency in the conveyor route when a no-denomination detection signal NE is outputted by the timer circuit 125 to be described below. The conveyor control unit 121 then stops the conveyor drive unit 120. In addition, 126 denotes the conveyed paper currency detection unit that detects the notes of paper currency conveyed by the conveyor drive unit 120 using an optical device. The timer circuit 125 inputs the conveyed paper currency detection signal TN from the conveyed paper currency detection unit 126. If a conveyed paper currency detection signal TN is not inputted within a specific interval of time, a control signal is outputted from the conveyor control unit 120 and a no-denomination detection signal is outputted.

The mode selection unit 127 is used to select the processing mode. The device counts notes of paper currency until there are no more notes of paper currency left in the loading unit 2. At this time, the conveyor drive unit 120 is automatically stopped by a count termination signal CF from the count completion detection unit 128 by way of the conveyor control unit 121. The second paper currency capacity detection unit 129 detects paper currency conveyed over the paper currency collection platform 23.

The counting unit 200 comprises an add gate 201, a first memory 202 consisting of registers 202A-202D, a main memory 203, and an addition control unit 204. The denomination signals from the denomination storage unit 113 and the paper currency detection signals from the conveyed paper currency detection unit 126 are used to count the number of notes by denomination. When the count termination signal CF is received, the results are added together in the main memory 203. The data in the first memory 202 and the main memory 203 are displayed with the data for converting this data to total amounts using the display unit 101. The first memory 202 consists of registers 202A-202D for the 500-yen, 1000 yen, 5000 yen, and 10,000-yen denominations. The total number of notes by denomination is stored in the memory. When mixed denomination totals are calculated, the denomination selection keys 103 and the operation mode selection buttons 106 are used. The function keys are used to display these mixed totals on the display unit

101 by way of the addition control unit 204. Like the first memory 202, the main memory 203 has memory units for the four denominations 500 yen, 1000 yen, 5000 yen, 10,000 yen to store the totals. The denomination selection keys 103 and the total key 107 (i.e. function keys) are used to display the stored data on the display unit 101. In the case of common paper calculations and single denomination calculations, the addition control unit 204 stores the calculations by denomination in the first memory 202 via the add gate 201, converts this data to the various totals, and sends this with the denomination number of notes data to the display unit 101 for display. In the case of multiple denomination calculations, the denomination calculation data stored in the first memory 202 is converted to total amount data using the denomination selection keys 103 and the subtotal key 108, and then sent with the denomination number of notes data to the display unit 101 for display. When the subtotal key 108 is used, the addition control unit 204 adds the data in the first memory 202 to the denomination units in the main memory 203. The denomination data stored in the main memory 203 is converted to total data by using the denomination selection keys 103 and the total key 107. In the case of batch mode, the denomination data in the first memory 202 is batched based on input from the note number setting unit 104, and a match signal CN is outputted when the calculation matches the input.

When the total key 107 is used to indicate a data display for the main memory 203, a main memory display command is applied to the addition control unit 204 by operating the denomination selection keys 103 beforehand. When the subtotal key 108 is used to indicate a data display for the first memory 202 or a display adding the data in the first memory 202 to the main memory 203, an addition command is applied to the addition control unit 204 by operating the denomination selection keys 103 beforehand. The display 101 is divided into a number of notes display 101A and a total amount of money display 101B. In the case of single denominations (or common paper), the denomination total is displayed along with the total number of notes. In the case of mixed denominations (in which the totals are retrieved), the denomination data is displayed based on specific operations. Because the mode selection unit 127 inputs signals from the denomination count selection button 105 and the operation mode selection button 106 and outputs mode signals MS to perform calculations, when the batch mode is selected and when common paper is selected in the calculation or addition mode, the identifier 112, denomination selection keys 103 and denomination

storage unit 113 are deactivated, and the paper currency detection signals outputted from the conveyed paper currency detection unit 126 are used to calculate the number of notes in the 10,000 yen denomination register 202A.

The operation mode selection buttons 106 are used to select one of three calculation modes: (1) count mode for counting the total number of notes for a common paper calculation and the total number of notes and total amount of money for single and multiple denomination calculations in which the count proceeds until there are no more notes left in the loading unit 2 at which time the conveyor drive unit 120 is shut down automatically by a count termination signal CF from the count completion detection unit 128; (2) an addition mode in which the notes of paper currency in the loading unit 2 are counted one by one with the data displayed in the denomination registers 202A-202D during the count and the data totaled in the denomination registers 202A-202D and the total number of notes for a common paper calculation and the total number of notes and total amount of money for single and multiple denomination calculations displayed when the count termination signal CF is outputted; and (3) batch mode in which a match signal CN is inputted to the count completion detection unit 128 when the notes of paper currency in the paper currency collection platform 23 detected by the paper currency capacity detection unit 129 match the number of notes set using the note number setting unit 104, the paper currency in the paper currency collection platform 23 is extracted, the conveyor drive unit 120 resumes operation with the set number of notes calculated and displayed, and in which the conveyor drive unit 120 stops when the set number of notes has not been reached and a no-denomination detection signal NE is outputted and the conveyor drive unit 120 does not resume operation until additional notes have been placed in the loading unit 2.

The following is an explanation of the operation of this device when notes of a single denomination of paper currency are counted in addition mode.

First, "single denomination" is selected using the denomination count selection buttons 105 and "addition mode" is selected using the operation mode selection buttons 106. When the denomination of paper currency to be counted has been selected using the denomination selection key 103, a selected

denomination signal is outputted from the particular denomination selection key 103. In this case, the "10,000" yen denomination has been selected.

When the bundles of paper currency to be counted are placed in the loading unit 2, the paper currency is detected by the paper currency capacity detection unit 122 and a detection signal is inputted to the conveyor control unit 121 as a start command. The conveyor control unit 121 outputs control signals to operate the conveyor drive unit 120, and the notes of paper currency in the loading unit 2 are then one by one extracted and conveyed by the conveyor belt 3.

Because the pattern detection unit 111 is situated between the loading unit 2 and the conveyed paper currency detection unit 126, the pattern of the conveyed paper currency is detected by the pattern detection unit 111, and pattern detection signals are outputted. Based on this input, the identifier 112 outputs identification signals indicating the 10,000-yen denomination. The denomination collation unit 114 inputs and collates these identification signals with the denomination signals from the denomination selection key 103, and outputs a "match" or "mismatch" collation signal RF. If the collation signal is a "mismatch" signal, the conveyor control unit 121 stops the conveyor drive unit 120. The wrong denomination paper currency discharge unit 123 may also be operated without shutting down the conveyor drive unit 120 so as to discharge the note with the wrong denomination instead of conveying it to the paper currency collection platform 23.

The conveyed paper currency is conveyed from the location where the pattern detection unit 111 is situated to the location where the conveyed paper currency detection unit 126 is situated. The conveyed paper currency detection unit 126 outputs a single-pulse conveyed paper currency detection signal TN as the note of paper currency passes. The conveyed paper currency detection signal TN is inputted to the add gate 201 in the counting unit 200. When a "match" collation signal RF has been inputted, the conveyed paper currency detection signal TN is inputted to the "10,000" yen register 202A corresponding to the denomination signal outputted from the denomination storage unit 113. The signal is counted. The number of notes counted is then displayed on the number of notes display unit 101A in the display unit 101. The

contents of the "10,000" yen register 202A changes the total in the addition control unit 204, and this is displayed in the total amount display unit 101B in the display unit 101. The notes of paper currency are extracted and conveyed one at a time, and are identified and counted one at a time. When there are not more notes of paper currency in the loading unit 2, the paper currency capacity detection unit 122 no longer detects notes of paper currency and no detection signals are outputted. Because notes of paper currency are no longer being detected by the conveyed paper currency detection unit 126, the timer circuit 125 outputs a no-currency signal after a specific amount of time has elapsed without receiving a conveyed paper currency detection signal TN. The count completion detection unit 128 outputs a count completion signal CF, the data in the first memory 202 is transferred to the main memory 203, and the conveyor drive unit 120 is shut down. If more notes of paper currency are placed in the loading unit 2, the same process is repeated.

The following is a description of the operation of the device when "multiple denominations" is selected using the denomination count selection button 105 and the "count mode" is selected using the operation mode selection button 106.

When a bundle of mixed denomination paper currency is placed in the loading unit 2, the conveyor drive unit 120 is activated, the notes of paper currency are extracted and conveyed one at a time, and the pattern detection unit 111 outputs a pattern detection signal to identify the denomination of the conveyed paper currency. The identifier 112 outputs the identification signal indicating the denomination, and the denomination collation unit 114 inputs the mode signal MS from the mode selection unit 127 and does not operate. The add gate 101 inputs the conveyed paper currency detection signal TN from the conveyed paper currency detection unit 126 corresponding to the denomination signal to the register 202A-202D in the first memory 202 corresponding to the denomination. The number of notes for each denomination and the total amount of money are shown in the number of notes display unit 101A and the total amount display unit 101B in the display unit 101. Display units 101 with a single display mean can be designed to display the number of notes per denomination in successive order using separate denomination display keys. The display unit can also be equipped with display means corresponding to each denomination register.

The display for the total amount of money is similar.

When the "addition mode" is selected and there is no longer any mixed denomination paper currency in the loading unit 2, a count termination signal CF is outputted from the count completion detection unit 128. The addition control unit 204 adds the contents of the denomination registers 202A-202D, and displays the contents of the total count circuit in the main memory 203 on the display unit 101 in number of notes and total amount of money. When another bundle of paper currency is placed in the loading unit 2, the conveyor drive unit 120 is automatically activated. The number of notes is tallied in the registers 202A-202D by means of the add gate 201 and then displayed on the display unit 101. When the tally is complete, the total number of notes per denomination and the total amount of money are displayed. When "mixed denomination" or "single denomination" is selected and the denomination to be counted is selected using the denomination selection keys 103, the identification signals from the identifier 112 are collated by the denomination collation unit 114. Notes of paper currency of other denominations may be discharged to the discharge unit. Only notes of paper currency with the selected denomination(s) are conveyed to the paper currency collection platform 23 and counted by denomination.

When "common paper" or "batch mode" is selected, denomination identification is not performed and the denomination selection keys 103 are locked.

In this preferred embodiment, the denomination selected using the denomination selection keys 103 is stored in the denomination storage unit 113, and the denomination collation unit 114 collated the stored denomination. However, the denomination identified initially by the identifier 112 can be stored in the denomination storage unit 113 and then inputted to the denomination collation unit 114. In the preferred embodiment, notes of paper currency were counted. The process is the same for other denominations of paper currency.
